Contamination is anything that doesn't belong in the fluid. Particulate contaminants are the most common. These include dirt, metals, weld spatter, paint flakes, rag fibers and sealing materials, but can be as small as a few microns. A micron is one millionth of a meter.

Heat, water, air and other fluids are also contaminants. These combine to break down the oil's chemical composition, forming harmful oil oxidation and acids.

Particle contamination and oil chemical degradation can lead to premature machine damage. Using contamination control not only reduces these damaging effects, but provides improved component performance, extended component life and reduced downtime. By using OEM standards for Cat, Peterson provides parts that may share the same numbers as our competitors but are a completely different quality.

PARTS STORAGE

Parts remain in the original packaging until you buy them to preserve the integrity of each part by keeping the contaminants out.

O-rings are kept in plastic bags in an enclosed cabinet to ensure that there are two barriers to contaminants.

Filter boxes remain clean and unopened because boxes that have remained glued shut or shrink wrapped can assure you that the filters have been protected since they were manufactured.

Fluid carrying hoses are stored with end caps in place to prevent hoses from collecting contaminants in storage so dust and such doesn't make its way into your machinery after purchase.

All parts and their storage bins are kept clean and delivered to you in that manner because every customer deserves the highest quality care for their parts.
